

**ADENOSINE RECEPTOR ANTAGONISTS AND METHODS OF MAKING AND
USING THE SAME**

CROSS-REFERENCE TO RELATED APPLICATIONS

This application claims priority from U.S. Provisional Application Serial No.
5 60/165,191, filed on November 12, 1999.

BACKGROUND OF THE INVENTION

The invention relates to antagonists of the adenosine receptors and methods of making and using the same in the treatment of diseases.

Adenosine is an intracellular and extracellular messenger generated by all cells in the
10 body. It is also generated extracellularly by enzymatic conversion. Adenosine binds to and activates seven transmembrane G-protein coupled receptors, eliciting a variety of physiological responses. Adenosine itself, substances that mimic the actions of adenosine (agonists), and substances that antagonize its actions have important clinical applications. Adenosine receptors are divided into four known subtypes (i.e., A₁, A_{2a}, A_{2b}, and A₃). These
15 subtypes elicit unique and sometimes opposing effects. Activation of the adenosine A₁ receptor, for example, elicits an increase in renal vascular resistance while activation of the adenosine A_{2a} receptor elicits a decrease in renal vascular resistance.

In most organ systems, periods of metabolic stress result in significant increases in the concentration of adenosine in the tissue. The heart, for instance, produces and releases
20 adenosine to mediate adaptive responses to stress, such as reductions in heart rate and coronary vasodilatation. Likewise, adenosine concentrations in kidneys increase in response to hypoxia, metabolic stress and many nephrotoxic substances. The kidneys also produce adenosine constitutively. The kidneys adjust the amount of constitutively produced adenosine in order to regulate glomerular filtration and electrolyte reabsorption. Regarding
25 control of glomerular filtration, activation of A₁ receptors leads to constriction of afferent arterioles while activation of A_{2a} receptors leads to dilatation of efferent arterioles. Activation of A_{2a} receptors may also exert vasodilatory effects on the afferent arteriole. Overall, the effect of activation of these glomerular adenosine receptors is to reduce

glomerular filtration rate. In addition, A₁ adenosine receptors are located in the proximal tubule and distal tubular sites. Activation of these receptors stimulates sodium reabsorption from the tubular lumen. Accordingly, blocking the effects of adenosine on these receptors will produce a rise in glomerular filtration rate and an increase in sodium excretion.

SUMMARY OF THE INVENTION

The invention is based on the discovery that compounds of Formula I are unexpectedly highly potent and selective inhibitors of particular subtypes of adenosine receptors. DESCRIPTION OF THE PREFERRED EMBODIMENTS

In general, the invention features highly potent and selective antagonists of the adenosine A₁ receptor. Selective antagonists of the adenosine A_{2a} receptor are also disclosed.
Synthesis of the Adenosine Antagonist Compounds

The compounds of the invention may be prepared by a number of known methods. Two general methods are described herein. Each of them employs a common starting material, 1,3-disubstituted-5,6-diaminouracil (compound (VI)), as shown in the two schemes below. 1,3-Disubstituted-5,6-diaminouracils can be prepared by treating the corresponding symmetrically or unsymmetrically substituted urea with cyanoacetic acid, followed by nitrosation and reduction (see, e.g., *J. Org. Chem.* **16**, 1879, 1951; *Can J. Chem.* **46**, 3413, 1968, incorporated herein by reference). Unsymmetrically substituted xanthines can be accessed via the method of Mueller (*J. Med. Chem.* **36**, 3341, 1993, incorporated herein by reference). In this method, 6-aminouracil is monoalkylated specifically at N3 of the uracil under Vorbruggen conditions. Alternatively, unsubstituted N1 or N3 position can be functionalized (e.g., alkylation) in the last stage of synthesis.

In the first general method, a 1,3-disubstituted-5,6-diaminouracil (compound (VI)) can first undergo a ring closure reaction to produce a xanthine intermediate that is unsubstituted at the 8-position. This intermediate, in turn, can couple with a precursor compound of the Z-R₃ moiety to produce the desired 8-substituted xanthines. Referring to scheme 1 below, the starting material 1,3-disubstituted-5,6-diaminouracil (i.e., compound (VI)) first reacts with HC(OEt)₃ to undergo a ring closure reaction to produce a xanthine intermediate that is unsubstituted at the 8-position (i.e., compound (A)). This intermediate, after being protected by an amino protecting group (e.g., with THP or BOM at the N7 position), further undergoes a coupling reaction, in the presence of a strong base (e.g., n-butyl-lithium (nBuLi) or lithium di-isopropyl-amide (LDA)), with a precursor compound of the Z-R₃ moiety (e.g., an aldehyde or a ketone) to produce an alcohol (i.e., compound (C)).

The hydroxyl group of the alcohol can then be reacted to convert the alcohol to an amine, a mercaptan, an ether, a lactone (e.g., compound (E)), or other functionalized compound, by methods well known to those of ordinary skill in the art. The N7 protection can then be removed to obtain a deprotected product (i.e., compound (F)), which can be further functionalized to yield compounds of this invention. See, e.g., Examples 1-6, 51, and 52.

Scheme 1

In the second general method, compounds of the invention can be prepared by reacting the starting material, a 1,3-disubstituted-5,6-diaminouracil, with a precursor

compound of the Z-R₃ moiety (e.g., aldehydes or carboxylic acids or carboxylic acid chlorides) to form a 6-amide substituted uracil intermediate, which in turn, can undergo a ring closure reaction to yield to a desired xanthine compound. Referring to scheme 2 below, the starting material 1,3-disubstituted-5,6-diaminouracil (i.e., compound (VI)) first couples with a di-carboxyl/ester-substituted precursor compound of the Z-R₃ moiety, HOOC-Z-R₃-COOR_a (i.e., compound (G)); R_a represents H, C₁₋₅ alkyl, or benzyl, the phenyl ring being optionally substituted with 1-3 substituents selected from the group consisting of halo, hydroxyl, or C₁₋₃ alkoxy) to yield a 6-amide substituted uracil intermediate (i.e., compound (H)) by reactions which are well known to one of ordinary skill in the art (e.g., by employing coupling reagents such as benzotriazol-1-yloxytris(dimethylamino)-phosphonium hexafluorophosphate (BOP), *O*-benzo-triazol-1-yl-*N,N,N',N'*-tetramethyluronium hexafluorophosphate (HBTU), or *O*-(7-azabenzotriazol-1-yl)-*N,N,N',N'*-tetramethyluronium hexafluorophosphate (HATU)). Examples of compound (G) include bicyclo[3.2.1]octane-1,5-dicarboxylic acid monomethyl ester and bicyclo[2.2.2]octane-1,4-dicarboxylic acid monoethyl ester. See, e.g., Examples 8 and 13. The uracil intermediate can then undergo a ring closure reaction in a basic condition (e.g., by employing KOH and isopropyl alcohol) to yield a xanthine compound (i.e., compound (J)), which can undergo further functionalization to produce various compounds of the invention.

The desired aldehydes, ketones, carboxylic acids and carboxylic acid chlorides are commercially available (e.g., from Aldrich Chemical Co., Inc., Milwaukee, Wisc.) or can be readily prepared from commercially available materials by well-known synthetic methods. Such synthetic methods include, but are not limited to, oxidation, reduction, hydrolysis, alkylation and Wittig homologation reactions. For references regarding the preparation of bicycloalkane carboxylic acids of the invention (e.g., compound (III), which is an example of compound (G)), see, e.g., *Aust. J. Chem.* **38**, 1705, 1985; *Aust. J. Chem.* **39**, 2061, 1986; *J. Am. Chem. Soc.* **75**, 637, 1953; *J. Am. Chem. Soc.* **86**, 5183, 1964; *J. Am. Chem. Soc.* **102**, 6862, 1980; *J. Org. Chem.* **46**, 4795, 1981; and *J. Org. Chem.* **60**, 6873, 1995.

In one instance, when compound (G) is bicyclo[2.2.2]octane-1,4-dicarboxylic acid or its corresponding esters (wherein Z is a single bond and R₃ is bicyclo[2.2.2]octyl), there are a number of different methods for their preparation. Referring to FIG. 2, the starting material (i.e., compound (I)) is a 1-COOR_a-4-COOR_b-cyclohexane, wherein each of R_a and R_b, independently, represents H, C₁₋₅ alkyl, or benzyl, the phenyl ring being optionally substituted with 1-3 substituents selected from the group consisting of halo, hydroxyl, or C₁₋₃ alkoxy. Preferably, R_a and R_b are identical and represent methyl or ethyl. Three different synthetic routes are illustrated in Fig. 2 for the transformation of compound (I) to compound (III) (an example of compound (G)). Route (1) (i.e., steps (A) and (B)) involves transforming compound (I) to its corresponding chloroethyl-containing compound (II), which in turn, undergoes a ring closure reaction to form the corresponding 1,4-bicyclo[2.2.2]octane acid/ester (III). See Examples 79 and 80. Route (2) also involves compound (II), which is transformed to compound (III) via another intermediate, compound (XXV), the iodoethyl-containing derivative of compound (I). See Examples 101 and 102. Route (3) (i.e., step (TT)) involves the transformation of compound (I) to the 1,4-bicyclo[2.2.2]octane acid/ester (III) without isolating the intermediates, i.e., compound (II). See Example 110.

To prepare compound (II), the starting material compound (I) is treated with about 1 to about 1.5 equivalents of a strong base. Strong bases that can be employed in this reaction include lithium diisopropylamide (LDA) and lithium isopropylcyclohexylamide, with LDA being the preferred base. Typical solvents for this reaction include tetrahydrofuran (THF), dimethoxyethane, dioxane, and t-butyl methyl ether, with THF being the preferred solvent. This reaction should be performed in a temperature range of about -100°C to about -60°C. The reaction mixture is then treated with about 1 to about 1.5 equivalents of

bromochloroethane in the presence of at least four equivalents of a reagent such as 1,1,3,3-tetramethylurea (TMU), 1,3-dimethyl-3,4,5,6-tetrahydro-2(1H)-pyrimidinone (DMPU), 15-crown-5, and 12-crown-4, with TMU being preferred. This reaction can be conducted in solvents such as THF, dimethoxyethane, dioxane, or t-butyl methyl ether (with THF being the preferred solvent) and at temperature ranging from about -80°C to about 0°C. Ring closure reaction can be performed by first treating compound (II) with about four equivalents of hexylmethylphosphoramidate (HMPA), which is then followed by treatment with a strong base such as n-butyllithium and diisopropylamine (DIEA).

Turning to route (2), the chloroethyl-containing intermediate (II) can be treated with iodide to form the desired iodoethyl-containing intermediate (XXV). Examples of iodide that can be employed in this reaction include sodium iodide, potassium iodide, lithium iodide, or tetrabutylammonium iodide, with NaI being the preferred iodide. Ring closure reaction is then conducted in the presence of a suitable strong base such as LDA or lithium isopropylcyclohexylamide (with LDA being the preferred base) and reagents such as TMU or DMPU. Typical solvents for use in this reaction include THF, dimethoxyethane, dioxane, or t-butyl methyl ether (with THF being preferred). This reaction should be conducted at a temperature ranging from about -80°C to about 25°C.

Referring to route (3) in which the starting material compound (I) is converted directly to compound (III), compound (I) is first treated with about 1 to about 1.5 equivalents of a strong base such as LDA or lithium isopropylcyclohexylamide (with LDA being the preferred base) in a suitable solvent such as THF, dimethoxyethane, dioxane, t-butyl methyl ether (with THF being the preferred solvent). The temperature of the reaction should range from about -100°C to about -60°C. The resulting reaction mixture is then treated with less than one equivalent of bromochloroethane in the presence of at least four equivalents of HMPA at a temperature ranging from about -80°C to about 25°C. The resulting reaction mixture is further contacted with about 1 to about 1.5 equivalents of a strong base such as LDA or lithium isopropylcyclohexylamide (with LDA being the preferred base) and at least four equivalents of HMPA in a suitable solvent such as THF, dimethoxyethane, dioxane, or t-butyl methyl ether (with THF being the preferred solvent). This reaction should be conducted at a temperature ranging from about -100°C to about -60°C. Note that no isolation of intermediates are needed in route (3).

There are many methods to further functionalize compound (J), which contains a carboxylic acid or ester attached to the R_3 moiety. For example, compound (J) can be converted to the corresponding acrylic acid derivative. One way is to first hydrolyze the ester group of compound (J) (provided that R_a is not H) to give the corresponding carboxylic acid, reduce the carboxylic acid to the corresponding alcohol, oxidize the alcohol to the corresponding aldehyde, and then perform a Wadsworth-Horner-Emmons or Wittig reaction to form the corresponding acrylic acid derivative. See, e.g., Examples 5, 6, 15, 16, and 17. Compound (J) can also be transformed directly to its corresponding alcohol (see, e.g., Example 4). A different variation is to transform compound (J) directly to its corresponding aldehyde. A further variation, is to transform an ester-containing compound (J) to its corresponding carboxylic acid, and then directly to the aldehyde. Alternatively, one can functionalize the precursor compound of the Z- R_3 moiety before coupling to the or 1,3-disubstituted-8-unsubstituted xanthine in scheme 1 or the 1,3-disubstituted-5,6-diaminouracil in scheme 2. Further, compounds of this invention can be prepared on solid support (e.g., Wang resin). See Example 36.

FIG. 3 discloses an alternative process to prepare compound (XIV) starting with compound (IV). The process illustrated in FIG. 2 employs similar chemistry as illustrated in FIG. 2 but first prepares the propionic acid side chain on the bicyclo[2.2.2]octyl moiety and then adds on the 1,3-di-substituted uracil moiety followed by cyclization to give the desired compound (XIV). With regard to compound (XX), R_3 and R_4 must be chemically different in their reactivity (e.g., methyl and benzyl).

FIG. 4 discloses an alternative processes for the transformation of compound (VII) to the corresponding alcohol (X) and the subsequent transformation of the alcohol (X) to the olefin (XII). Steps (F') thru (H) are ring closure followed by saponification of the ester (VIII) to the acid (IX) followed by reduction to the alcohol (X), see Examples 84, 85, and 86. Alternatively, compound (VII) can undergo reduction (step (Y), see Example 103) and cyclization reactions to produce compound (X) (step (Z), see, e.g., Example 84a). A further alternative way involves saponification and cyclization of compound (VII) to produce compound (IX) (steps (Y') and (Z')). These reactions are well known to those skilled in the art. See, e.g., Examples 85a and 84a. Steps (I) thru (DD) disclose alternative processes for the transformation of the alcohol (X) to the corresponding olefin (XII). Specifically, steps (J), (AA) and (CC) (see Examples 89, 104, and 105) are alternative ways of transforming the

one carbon aldehyde of compound (XI) to the acrylic acid/ester-containing moiety by means known to those skilled in the art.

Referring to FIG. 5, compounds (XXIX) and (XXX) have been previously described in the literature (Grob, C.A., Rich, R. *Helv. Chim. Acta.* **1979**, *62*, 2802; Ahmed, S.A., Hickmott, P.W. *J. Chem. Soc. Perkin Trans. I*, **1979**, 2180) (i.e., Steps (EE) and (FF)). Compound (XXX) can be converted to compound (XXXI) by well-known methods. For example, compound (XXX) may be reduced directly by means of a Wolff-Kishner or Clemmenson reduction. Alternatively, the ketone functionality of compound (XXX) may first be converted to a dithioketal derivative, such as for example, a 1,3-dithiane, 1,3-dithiolane or 1,3-dialkylthioketal. This intermediate, would, in turn, be desulfurized by Raney-Ni. Functional group manipulations of this sort are common and are known to one of average skill in the art. The following two steps, i.e., steps (GG) and (HH), represent examples of coupling a 1,3-disubstituted-5,6-diaminouracil with a carboxylic acid followed by base-mediated ring closure. In Step (II), the tertiary hydroxyl is converted to its corresponding bromide, iodide or trifluoromethanesulfonate by exposure to PBr₃, TMSBr, TMSI, KI and H₃PO₄, or trifluoromethanesulfonic anhydride in the presence of a non-nucleophilic base. Compound (XXXV) would then be formed by treatment of (XXXIV) with a catalyst derived from a palladium salt (Pd(OAc)₂, PdCl₂, Pd(O₂CCF₃)₂, etc.) and a phosphine ligand (PPh₃, P(o-tolyl)₃, etc.) followed by treatment with an olefin (such as methyl acrylate, methylpropiolate, etc.). Hydrogenation of compound (XXXV) followed by conversion of the ester to the corresponding acid would provide compound (XIV). Alternatively, the ester could first be converted to the acid and the hydrogenation then performed to also generate (XIV).

FIG. 6 discloses a process to prepare acid (compound (XXI)) which is the starting material for FIG. 3. In step (LL), treatment of compound (XXXI) with trifluoromethanesulfonic anhydride in the presence of a base such as pyridine affords XXXVI (R_g = OTf). The next step, i.e., step (MM), involves treating compound (XXXVI) (R_g = OTf) with a catalyst derived from a palladium salt (Pd(OAc)₂, PdCl₂, Pd(O₂CCF₃)₂, etc.) and a phosphine ligand (PPh₃, P(o-tolyl)₃, etc.), which is then followed by exposure to an olefin (methyl acrylate, methyl propiolate, etc.) to afford compound (XXXVII) (wherein M = -C≡C- or -CH=CH-). In step (NN), compound (XXXVII) undergoes hydrogenation with palladium on carbon under an atmosphere of hydrogen to yield compound (XXI).

Turning to FIG. 7, compound (X) can be converted to compound (XL) containing a leaving group (LG) such as, e.g., halo (Cl, Br, or I), mesylate, nosylate, tosylate, and trifluoromethanesulfonate. The leaving group (LG) can then be displaced by a malonic ester, such as, e.g., dimethyl malonate, in the presence of a base, such as, e.g., methoxide. The leaving group (LG) might also be displaced by Meldrum's acid, in the presence of a base such as methoxide. Conversion of the esters or the cyclic anhydride, in the case of Meldrum's acid, to the corresponding acids followed by decarboxylation provides compound (XXXV).

FIG. 8 discloses an overview of the synthetic methods that can be employed to produce various compounds of the invention. In step 1, treatment of compound 7-1 (Z = Br, I or OTf, and R = H, tetrahydropyran-2-yl- or 1-pyrrolidinylmethyl) with a catalyst derived from a palladium salt ($\text{Pd}(\text{OAc})_2$, PdCl_2 , $\text{Pd}(\text{O}_2\text{CCF}_3)_2$, etc.) and a phosphine ligand (PPh_3 , $\text{P}(\text{o-tolyl})_3$, etc.) is followed by exposure to compound 7-2 (X = Li, ZnCl, MgBr, SnBu₃, B(OH)₂ and R' = CO₂H, CO₂Me, CO₂Et, C≡CCO₂Me, C≡CCO₂Et, CH=CHCO₂Me, CH=CHCO₂Et, CH₂CH₂CO₂Me, CH₂CH₂CO₂Et) to afford compound 7-3 (R = H, tetrahydropyran-2-yl- or 1-pyrrolidinylmethyl and R' = CO₂H, CO₂Me, CO₂Et, C≡CCO₂Me, C≡CCO₂Et, CH=CHCO₂Me, CH=CHCO₂Et, CH₂CH₂CO₂Me, CH₂CH₂CO₂Et). When R = tetrahydropyran-2-yl- or 1-pyrrolidinylmethyl treatment with acid (TFA, PPTS, HCl etc.) provides compound 7-3 where R = H. In step 2, treatment of compound 7-2 (Z = Br, I, or OTf, and R' = CO₂H, CO₂Me, CO₂Et, C≡CCO₂Me, C≡CCO₂Et, CH=CHCO₂Me, CH=CHCO₂Et, CH₂CH₂CO₂Me, CH₂CH₂CO₂Et) with a catalyst derived from a palladium salt ($\text{Pd}(\text{OAc})_2$, PdCl_2 , $\text{Pd}(\text{O}_2\text{CCF}_3)_2$, etc.) and a phosphine ligand (PPh_3 , $\text{P}(\text{o-tolyl})_3$, etc.) is followed by exposure to compound 7-1 (X = Li, ZnCl, MgBr, SnBu₃, B(OH)₂ and R = tetrahydropyran-2-yl- or 1-pyrrolidinylmethyl) to afford compound 7-3 (R = tetrahydropyran-2-yl- or 1-pyrrolidinylmethyl and R' = CO₂H, CO₂Me, CO₂Et, C≡CCO₂Me, C≡CCO₂Et, CH=CHCO₂Me, CH=CHCO₂Et, CH₂CH₂CO₂Me, CH₂CH₂CO₂Et). When R = tetrahydropyran-2-yl- or 1-pyrrolidinylmethyl treatment with acid (TFA, PPTS, HCl etc.) provides compound 7-3 where R = H. Step 3 discloses a HATU-mediated coupling reaction of diamino uracil moiety with bicyclo[2.2.2]octane acid (which has been described above). In step 4, treatment of compound 7-4 (X = Cl, Br, I) with a catalyst derived from a palladium salt ($\text{Pd}(\text{OAc})_2$, PdCl_2 , $\text{Pd}(\text{O}_2\text{CCF}_3)_2$, etc.) and a phosphine ligand (PPh_3 , $\text{P}(\text{o-tolyl})_3$, etc.) is followed by exposure to an olefin (methyl acrylate, methyl propiolate, allyl alcohol, etc.) to

afford compound 7-5 ($R' = C \equiv CCO_2Me$, $C \equiv CCO_2Et$, $CH=CHCO_2Me$, $CH=CHCO_2Et$, CH_2CH_2CHO , etc). Step 5 discloses a base-promoted cyclization of uracil 7-5 to a xanthine of type 7-3 (which has been described above). Similarly, the base-promoted cyclization of uracil 7-4 to a xanthine of type 7-6 in step 6 has been described above. In step 7, treatment of compound 7-6 ($X = Cl$, Br , I , OTf) with a catalyst derived from a palladium salt ($Pd(OAc)_2$, $PdCl_2$, $Pd(O_2CCF_3)_2$, etc.) and a phosphine ligand (PPh_3 , $P(o\text{-tolyl})_3$, etc.) is followed by exposure to an olefin (methyl acrylate, methyl propiolate, allyl alcohol, etc.) to afford compound 7-3 ($R = H$, $R' = C \equiv CCO_2Me$, $C \equiv CCO_2Et$, $CH=CHCO_2Me$, $CH=CHCO_2Et$, CH_2CH_2CHO , etc). Step 8 discloses oxidation of the terminal aldehyde group in compound 7-3 ($R = H$, $R' = CH_2CH_2CHO$) which is accomplished by standard means (a. $NaClO_2$, NaH_2PO_4 , 2-methyl-2-butene; b. $NaIO_4$; etc.)

Uses for the Adenosine Antagonist Compounds

Activation of adenosine receptors elicits many physiological responses, including reductions in renal blood flow, reductions in glomerular filtration rate, and increases in sodium reabsorption in kidney. Activation of adenosine receptors reduces heart rate, reduces conduction velocity, and reduces contractility. These, and the other effects of activation of

adenosine receptors in other organs, are normal regulatory processes. However, these effects become pathological in many disease states. Thus, adenosine antagonists have extensive application in both prevention and treatment of disease. Diseases that can be prevented and/or treated with adenosine receptor antagonists include any conditions (a) marked by the presence of an abnormal level of adenosine and/or (b) requiring for treatment the inhibition or stimulation of adenosine production and/or release. Such conditions include, but are not limited to, congestive heart failure, cardio-pulmonary resuscitation, hemorrhagic shock, and other cardiac and circulatory disorders; degenerative disorders of the central nervous system; respiratory disorders (e.g., bronchial asthma, allergic lung diseases); and many diseases for which diuretic treatment is indicated (e.g., acute and chronic renal failure, renal insufficiency, hypertension). Degenerative illnesses such as Parkinson's disease, depression, traumatic brain damage, post-stroke neurological deficit, neonatal brain trauma, dyslexia, hyperactivity, and cystic fibrosis have all been linked to adenosine receptor activity. Other conditions in which treatment with adenosine receptor antagonists can have therapeutic utility include cirrhotic ascites, neonatal apnea, renal failure associated with traditional diuretic therapy, diabetes, and asthma.

Additionally, applicants have discovered that the administration of highly selective and potent adenosine A₁ receptor antagonists, for example, can elicit a diuretic response when administered alone and can potentiate the diuretic response to traditional diuretics. In addition, administration of adenosine receptor antagonists with traditional diuretics attenuate the reduction of glomerular filtration rate induced by traditional diuretics. The claimed methods are applicable, for example, in edematous conditions, such as congestive heart failure and ascites.

Administration of the Adenosine Antagonist Compounds

The compounds can be administered to an animal (e.g., a mammal such as a human, non-human primate, horse, dog, cow, pig, sheep, goat, cat, mouse, rat, guinea pig, rabbit, hamster, gerbil, ferret, lizard, reptile, or bird). The compounds can be administered in any manner suitable for the administration of pharmaceutical compounds, including, but not limited to, pills, tablets, capsules, aerosols, suppositories, liquid formulations for ingestion or injection or for use as eye or ear drops, dietary supplements, and topical preparations. The compounds can be administered orally, intranasally, transdermally, intradermally, vaginally,

intraaurally, intraocularly, buccally, rectally, transmucosally, or via inhalation, implantation (e.g., surgically), or intravenous administration.

Optionally, the compounds can be administered in conjunction with a non-adenosine modifying pharmaceutical composition (e.g., in combination with a non-adenosine modifying diuretic as described, for example, in co-pending application PCT/US99/08879 filed April 23, 1999, incorporated herein by reference in its entirety).

The invention will be further described in the following examples, which do not limit the scope of the invention described in the claims.

5 **Assay Methodology**

One hundred eighty-four xanthine derivatives were prepared, having the structures indicated in FIG. 2. For some of these compounds, the K_i values for rat and human adenosine A_1 receptors and for human adenosine A_{2a} receptors were determined according to the following binding assay protocol. The ratio A_{2a}/A_1 was also calculated.

10 Materials

Adenosine deaminase and HEPES were purchased from Sigma (St. Louis, MO). Ham's F-12 cell culture medium and fetal bovine serum were purchased from GIBCO Life Technologies (Gaithersburg, MD). Antibiotic G-418, Falcon 150 mM culture plates and Costar 12-well culture plates were purchased from Fisher (Pittsburgh, PA). [^3H]CPX was
15 purchased from DuPont-New England Nuclear Research Products (Boston, MA). Penicillin/streptomycin antibiotic mixture was purchased from Mediatech (Washington, DC). The composition of HEPES-buffered Hank's solution was: 130 mM NaCl, 5.0 mM Cl, 1.5 mM CaCl_2 , 0.41 mM MgSO_4 , 0.49 mM Na_2HPO_4 , 0.44 mM KH_2PO_4 , 5.6 mM dextrose, and 5 mM HEPES (pH 7.4).

20 Membrane preparation

Rat A_1 Receptor: Membranes were prepared from rat cerebral cortex isolated from freshly euthanized rats. Tissues were homogenized in buffer A (10 mM EDTA, 10 mM Na-HEPES, pH 7.4) supplemented with protease inhibitors (10 $\mu\text{g}/\text{ml}$ benzamidine, 100 μM PMSF, and 2 $\mu\text{g}/\text{ml}$ each of aprotinin, pepstatin and leupeptin), and centrifuged at 20,000 x g
25 for 20 min. Pellets were resuspended and washed twice with buffer HE (10 mM Na-HEPES, 1 mM EDTA, pH 7.4, plus protease inhibitors). Final pellets were resuspended in buffer HE, supplemented with 10% (w/v) sucrose and protease inhibitors, and frozen in aliquots at -80°C. Protein concentrations were measured using BCA protein assay kit (Pierce).

Human A_1 Receptor: Human A_1 adenosine receptor cDNA was obtained by RT-PCR and subcloned into pcDNA3.1(Invitrogen). Stable transfection of CHO-K1 cells was
30 performed using LIPOFECTAMINE-PLUS (GIBCO-BRL) and colonies were selected in 1 mg/ml G418, and screened using radioligand binding assays. For membrane preparations,

CHO-K1 cells growing as monolayers in complete media (F12+10%FCS+1mg/ml G418) were washed in PBS and harvested in buffer A supplemented with protease inhibitors. Cells were homogenized, centrifuged, and washed twice with buffer HE as described above. Final pellets were stored in aliquots at -80°C.

5 Radioligand binding assays

Membranes (50µg membrane protein for rat A1ARs, and 25µg of CHO-K1 membrane protein for human A1ARs), radioligands and varying concentrations of competing ligands were incubated in triplicates in 0.1 ml buffer HE plus 2 units/ml adenosine deaminase for 2.5 h at 21°C. Radioligand [³H]DPCPX (112 Ci/mmol from NEN, final concentration: 1nM) was used for competition binding assays on A₁ARs. Nonspecific binding was measured in the presence of 10 µM BG9719. Binding assays were terminated by filtration over Whatman GF/C glass fiber filters using a BRANDEL cell harvester. Filters were rinsed three times with 3-4 ml ice-cold 10 mM Tris-HCl, pH 7.4 and 5 mM MgCl₂ at 4°C. Filter paper was transferred to a vial, and 3ml of scintillation cocktail ScintiVerseII (Fisher) was added. Radioactivity was counted in a Wallac β-counter.

15 Analysis of binding data

For K_i Determinations: Competition binding data were fit to a single-site binding model and plotted using Prism GraphPad. Cheng-Prusoff equation $K_i = IC_{50}/(1+[I]/K_D)$ was used to calculate K_i values from IC₅₀ values, where K_i is the affinity constant for the competing ligand, [I] is the concentration of the free radioligand, and K_D is the affinity constant for the radioligand.

For % Binding: For one-point binding assays, data were presented as % of total specific binding at 1µM of competing compound: % of total = 100* (Specific binding with 1 µM of competing compound/ total specific binding).

25 Results

All of the compounds tested exhibited rat A₁ K_i values between 0.6 and 433.8 nM, human A₁ K_i values between 1.6 and 1000 nM, and human A_{2a} K_i values between 132 and 49930 nM. All of the compounds had A_{2a}/A₁ ratios greater than 10, most greater than 20, many greater than 50, and some greater than 100. At least one compound had a A_{2a}/A₁ ratio greater than 1000.

Cell Culture

5 CHO cells stably expressing the recombinant human A₁AdoR (CHO:A₁AdoR cells) were prepared as described (Kollias-Barker et al., *J. Pharma. Exp. Ther.* **281**(2), 761, 1997) and cultured as for CHO:Wild cells. CHO cells were cultured as monolayers on plastic dishes in Ham's F-12 medium supplemented with 10% fetal bovine serum, 100 U penicillin G and 100 µg streptomycin in a humidified atmosphere of 5% CO₂/95% air at 37°C. The
10 density of [³H]CPX binding sites in CHO cells was 26 ± 2 (n=4) fmol/mg protein. Cells were subcultured twice weekly after detachment using 1 mM EDTA in Ca²⁺-Mg²⁺-free HEPES-buffered Hank's solution. Three different clones of CHO:A₁AdoR cells were used for experiments, and all results were confirmed with cells from two or three clones. The density of A₁AdoRs in these cells was 4000-8000 fmol/mg protein, as determined by assay of
15 [³H]CPX specific binding.

Radioligand Binding

CHO cells grown on 150 mm culture dishes were rinsed with HEPES-buffered Hank's solution, then removed with a cell scraper and homogenized in ice-cold 50 mM Tris-HCl, pH 7.4. Cell membranes were pelleted by centrifugation of the cell homogenate at
20 48,000 X g for 15 minutes. The membrane pellet was washed twice by resuspension in fresh buffer and centrifugation. The final pellet was resuspended in a small volume of 50 mM Tris-HCl, pH 7.4, and stored in aliquots of 1 ml at -80°C until used for assays.

To determine the density of A₁AdoRs in CHO cell membranes, 100 µl aliquots of membranes (5 µg protein) were incubated for 2 hours at 25°C with 0.15-20 nM [³H]CPX and
25 adenosine deaminase (2 U/ml) in 100 µl of 50 mM Tris-HCl, pH 7.4. Incubations were terminated by dilution with 4 ml of ice-cold 50 mM Tris-HCl buffer and immediate collection of membranes onto glass-fiber filters (Schleicher and Schuell, Keene, NH) by vacuum filtration (Brandel, Gaithersburg, MD). Filters were washed quickly three times with ice-cold buffer to remove unbound radioligand. Filter discs containing trapped
30 membranes bound radioligand were placed in 4 ml of Scintiverse BD (Fisher), and the radioactivity was quantified using a liquid scintillation counter. To determine nonspecific binding of [³H]CPX, membranes were incubated as described above and 10 µM CPT was

added to the incubation buffer. Nonspecific binding was defined as [³H]CPX bound in the presence of 10 μM CPT. Specific binding of the radioligand to the A₁AdoR was determined by subtracting nonspecific binding from total binding. Nonspecific binding was found to increase linearly with an increase of [³H]CPX concentration. Triplicate assays were done at each tested concentration of [³H]CPX.

To determine the affinities of antagonists of A₁AdoRs for the human recombinant A₁AdoR expressed in CHO cells, binding of 2 nM [³H]CPX in the presence of increasing concentrations of antagonist was measured. Aliquots of CHO cell membranes (100 μl: 5 μg protein), [³H]CPX, antagonist (0.1 nM – 100 μM), and adenosine deaminase (2 U/ml) were incubated for 3 hours at 25° C in 200 μl of 50 mM Tris-HCl buffer (pH 7.4). Assays were terminated as described above.

Data Analysis

Binding parameters (i.e., B_{max}, K_d, IC₅₀, K_i, and Hill coefficients) were determined using the radioligand binding analysis program LIGAND 4.0 (Elsevier-Biosoft).
